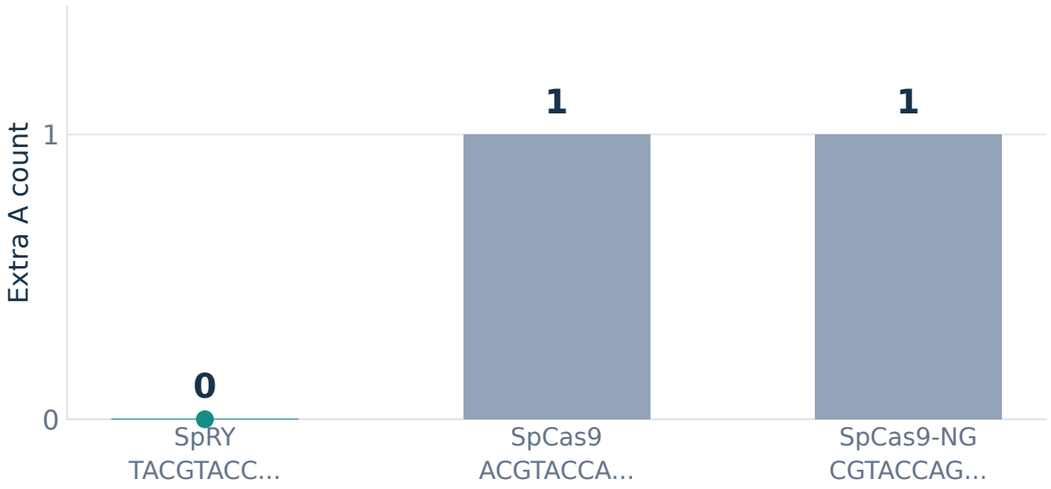
From window counts to position-weighted risk

HFE candidates | Different metrics are shown on separate scales

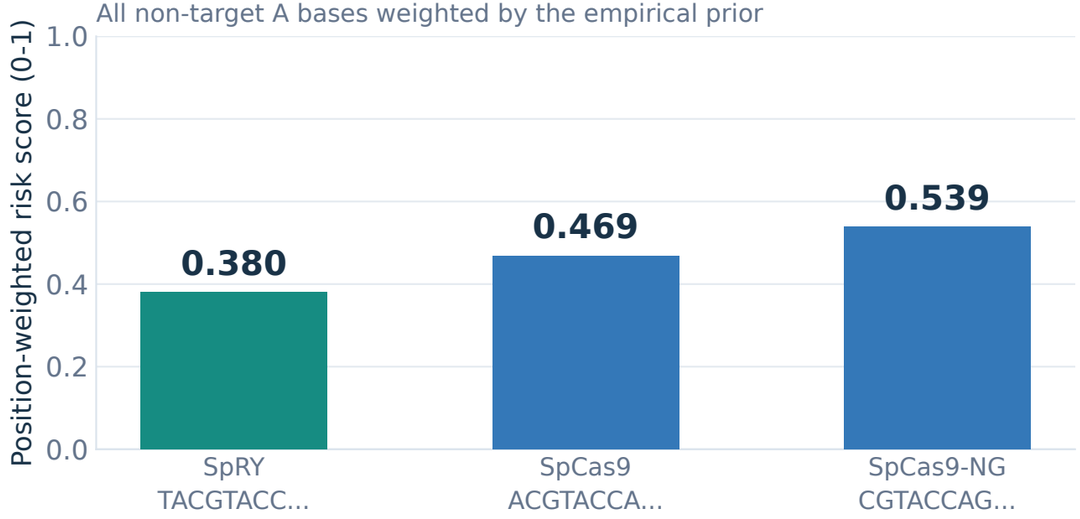
OLD | Window-based count

Non-target A bases at positions 4-8



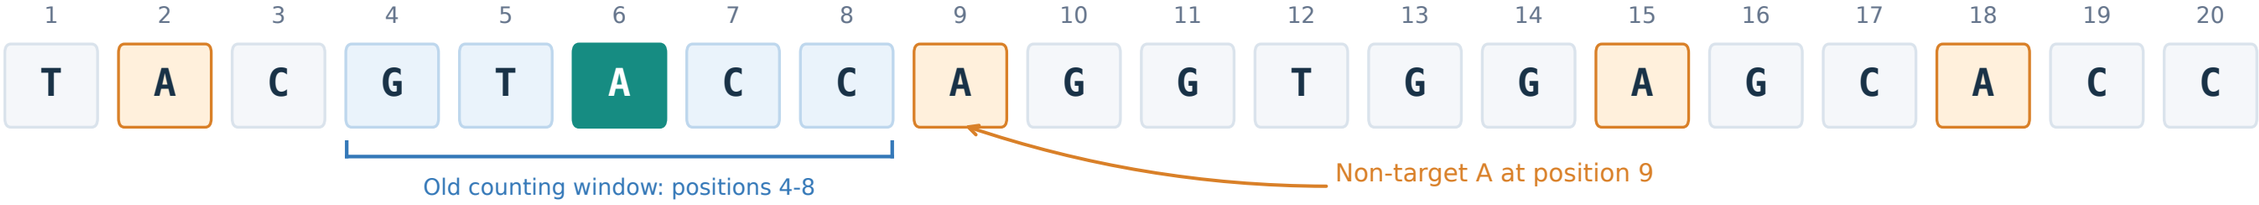
NEW | Position-weighted score

All non-target A bases weighted by the empirical prior



Why the SpRY example has count = 0 but score = 0.380

20-nt protospacer | Position 1 = PAM-distal



Target A: position 6

Excluded from the extra-A count | target weight = 1.000

Non-target A positions: 2, 9, 15, 18

Sum(non-target A weights) / (target weight + sum) = 0.380

Interpretation: zero extra A within positions 4-8 does not imply zero bystander risk. The weighted score is prior-based, not a measured editing frequency.
